

- Actor的管理，与spring的结合
- 流控
- 系统架构
- 性能测试数据

不频繁申请释放的大对象直接放到老年代

```
Class#newInstance();
```

创建一个由 `this` 代表的类的对象。该类以类似 `new A()` 的方式被实例化。该类会被初始化，如果没有过的话(诸如一些静态成员，静态初始化代码段)。此方法会传递所有由无参构造函数所产生的异常。该方法的调用会绕过本来会执行的编译器异常检查。`java.lang.reflect.Constructor#newInstance` 通过将构造函数抛出的异常包装在 `java.lang.reflect.InvocationTargetException` 中来避免这个问题。

```
DriverManager#getConnection(String url, java.util.Properties info) throws SQLException
```

对给定的数据库URL建立连接。`DriverManager`会试着从注册过的JDBC drivers中选择合适的driver。如果某个属性既在url指定了，又在properties中设置了，那么优先级会有具体实现(什么的实现？ driver?)决定。该函数会抛出`SQLException`(数据库访问错误)，和`SQLTimeoutException`(连接超时，诸如发了报文一直没有响应)。

```
Thread#getContextClassLoader()
```

返回这个线程的上下文类加载器(`ClassLoader`)。`ClassLoader`是由该线程的创建者提供，用来在线程代码执行前装载类和资源。如果没有调用 `setContextClassLoader` 设置加载器，默认使用父线程的`ClassLoader`。原始线程的`ClassLoader`一般设置为装载应用本身的类装载器(这是哪个?)。

```
driver.connect(url, info)
```

未提交读 `read uncommitted`，可以读到其他会话未提交的修改

提交读 `read committed`，只能读到已经提交的的修改

可重复读 `repeated read`，某查询在事务开始到提交期间都是一致的，不会因为本次事务的修改而改变，`innoDB`默认级别。

串行读 `serializable`，每次读都要获取表级共享锁，读写互相阻塞，`innoDB`默认行锁。

```
Object#await(long timeout)
```

```
PooledDataSource#popConnection
```

`mybatis`连接池获取连接，首先判断是否存在空闲连接，如果有，就从空闲连接池取出，如果没有就获取当前最老的活跃连接，判断其是否过期(`poolMaximumCheckoutTime`)，如果过期了，就注销`pooledConnect`(大概是`socket`连接的一层壳，用来标志某个应用获取的连接，找这块代码的意思，应用获取的每个连接的有效时间都不怎长啊，尽管最底层`tcp`连接是一直建着的长连接)

充值押金请求同时重复提交问题。随便充用户有一项属性是押金，每个用户的押金存在两种状态：1未充值 2已充值。假设当前用户未充值，此时同时有两个充值请求到来，先获取用户进行中的充值单，如果不存在，则创建一笔充值单。此时出现问题生成了两笔充值单。原因是innoDB默认隔离级别为repeated read，所以两笔事务同时select时都没有找到进行中的订单，这导致两个事务都会进行insert操作，而数据库并没有通过唯一键等手段来保证这个约束(同一用户同一时间只能有一笔进行中的充值订单)。

解决方法：

1. 要保证本地数据合法，最安全的是通过db本身提供的约束。给充值订单表添加字段 `active:Bool`，对active和userId建立联合唯一索引，进行中的订单active插入1，失效之后设置为null。
2. 由数据库保证本地数据合法是不够的，比如创建充值订单是会调用远端服务创建其他记录，在本地事务插入失败回滚的时候，远端的事务是没法回退的，当然通过脚本扫描数据库检查可以保证最终一致性。如果能保证相同user的押金充值请求是串行的，就可以简单高效的解决并发充值的问题，因此在引入akka库之后，创建router，使用ConsistentHashing按userId做分发，将充值请求分发到10000个worker actor上，在保证并发的同时确保同一用户的充值请求是串行处理的。性能分析记录在《xxxx》。

系统内所有类似select existence then do business的地方都有这个问题，通过在模块入口使用akka actor+定制路由的实现可以规避此类问题(当然也可以用BlockingQueue)，而对数据库设置严格的约束，可以保证上层业务系统无法对数据造成污染。再不济最后还有脚本检测数据一致性。

actor注意点,transcational不能直接用spring的，因为spring的事务基于threadlocal variable

- return code 与 exception 的选择

<https://stackoverflow.com/questions/99683/which-and-why-do-you-prefer-exceptions-or-return-codes>

exception优势有三：

1. 代码结构更清晰，错误处理不影响正常流程的代码
2. 异常不容易被函数调用方忽略，相比之下返回码更脆弱
3. 异常有类型化的，同一个函数可以抛出不同异常，相比之下返回值是类型确定而且单一的。

sqlsession, executor

binding 绑定 interface里面的函数-----MapperMethod & SqlCommand

MappedStatement 存储sql语句

```
[root@t1kvm01 lab]# jmap -histo 1387
```

bytes无法整除instances，因为有些bytes是用来字节对其的？

<https://docs.oracle.com/javase/specs/jvms/se7/html/jvms-4.html>

```
ClassFile {  
    u4          magic;  
    u2          minor_version;  
    u2          major_version;  
    u2          constant_pool_count;  
    cp_info     constant_pool[constant_pool_count-1];  
    u2          access_flags;  
    u2          this_class;  
    u2          super_class;  
    u2          interfaces_count;  
    u2          interfaces[interfaces_count];  
    u2          fields_count;  
    field_info  fields[fields_count];  
    u2          methods_count;  
    method_info methods[methods_count];  
    u2          attributes_count;  
    attribute_info attributes[attributes_count];  
}
```

field	value
magic	ca fe ba be
minor_version	00 00
major_version	00 34
constant_pool_count	00 27(常量池大小 39)

Q:把mybatis库引入之后，它是如何执行的呢？没有搜索到main()函数，那就只有通过spring加载了，如何加载？

A: SqlSessionFactoryBean为mybatis-spring的入口类

XMLConfigBuilder是mybatis的入口类之一 创建sqlSessionFactory 初始化configuration environment
transcationManager datasource

Q:调用dao接口时debug发现实现对象为MapperProxy，MapperProxy是何时生成&如何注入的？

在MapperProxy构造函数打断点，查看调用栈

```

```

A: 搜索业务代码使用的MapperScan注解，调用关系如下：

```

MapperScannerRegistrar$ImportBeanDefinitionRegistrar$registerBeanDefinitions<-
ConfigurationClassParser$processImports<-
ConfigurationClassPostProcessor$postProcessBeanDefinitionRegistry<-

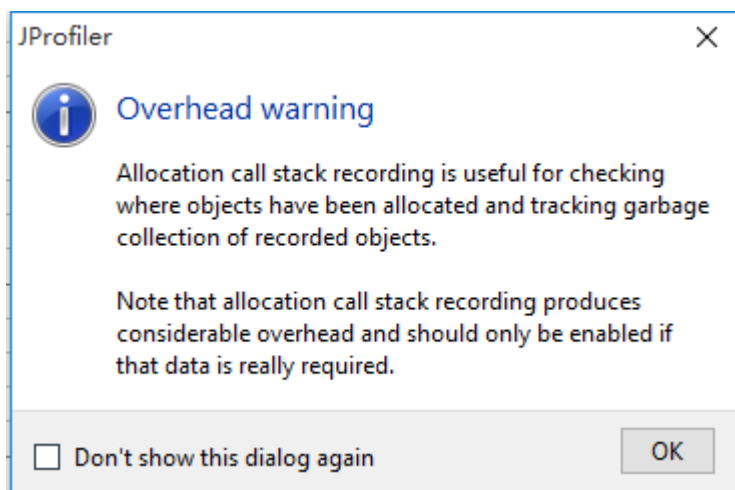

```

ImportBeanDefinitionRegistrar是spring提供的bean注册入口之一，spring搜索实现了该Interface的类，实例化并添加到importBeanDefinitionRegistrars中，后续处理中调用registerBeanDefinitions创建bean。

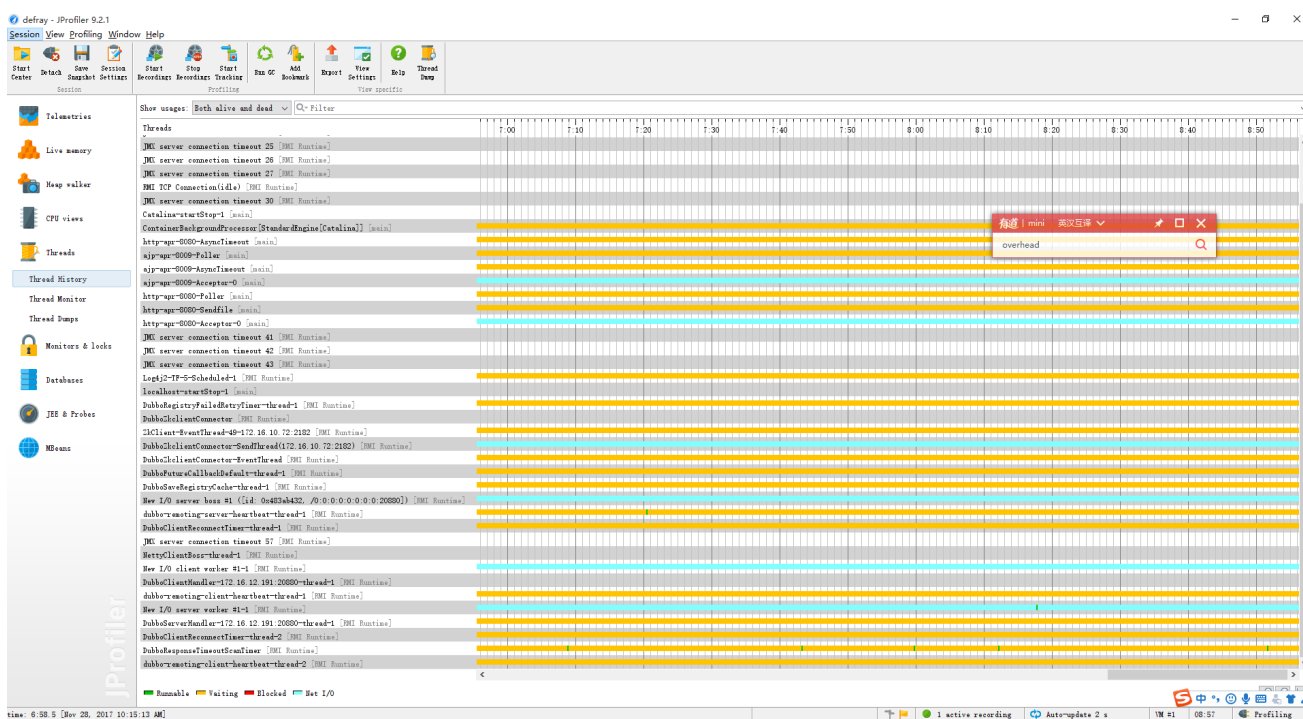

- Mybatis-spring的初始化通过spring提供的钩子ImportBeanDefinitionRegistrar实现，初始化内容包括加载SqlMapper，configuration，实现。而提供给向业务层的功能入口则是SqlSessionFactory，业务层通过创建SqlSessionFactory Bean来

loadContext spring入口函数

```
DubboComponentScanRegistrar
```

内存分配调用栈记录对于对象在哪分配和最终垃圾回收很有用，但是会产生相当一部分额外开销。

- 阅读mybatis,concurrentHashMap源码,部分spring-bean,spring-context源码,《深入理解java虚拟机》,《并发编程实践》,修改预防常见并发问题。
- dubbo 配置服务端方法级别 loadbalance, 配置不同protocol
- dubbo 服务端方法级别设置线程池, 编写扩展线程池, 根据参数做ConsistentHash, 以实现部分接口的串行化调用

```
ExtensionLoader.getExtensionLoader(ThreadPool.class).getAdaptiveExtension().getExecutor(url);
```

```
name.substring(0, name.length() - type.getSimpleName().length());
```

获取扩展名和key的映射
